

KPI	Definition	Formula / SQL
Revenue	Total sales value after discounts	$\text{SUM}(\text{total_value})$
AOV	Average revenue generated per order	$\text{Total Revenue} / \text{Number of Orders}$
Units Sold	Total number of products sold	$\text{SUM}(\text{quantity})$
Discount Rate	Proportion of sales given as discounts	$\text{Total Discount} / \text{Total Revenue} \times 100$
Customer Spend	Total amount spent by a customer	$\text{SUM}(\text{total_value})$ per customer
Repeat Purchase Rate	Percentage of customers purchasing more than once	$\text{Repeat Customers} / \text{Total Customers} \times 100$
Category Mix	Category's percentage of geographic revenue	$\text{Category Revenue} / \text{Total Revenue} \times 100$
MoM Revenue Change	Change in revenue from previous month	$(\text{Current} - \text{Previous}) / \text{Previous} \times 100$

Dataset Notes:

The **BM_SALES** table does not contain an **order_id**, so a true order-level AOV cannot be calculated from the provided schema. Repeat purchase analysis is based on multiple sales records per customer. The **BM_STORES** table contains **city** and **store_type**, but no **region** field; therefore, city is used as the geographic grouping. **BM_SALES** contains **discount_pct**, but does not contain **promo_id**; discounted sales are therefore used as a proxy for promotional sales.
